# A SIMPLE CORRELATION BETWEEN POINTS WITH ACTIVITY COEFFICIENT UNITY FOR 1:1 ELECTROLYTES AT 298 K 

I. Brandariz, T.Vilariño, J.L. Barriada, Manuel E. Sastre de Vicente ${ }^{* 1}$, Departamento de Química Física e Ingeniería Química I, Facultad de Ciencias, Universidad de la Coruña, Campus da Zapateira, s/n, E-15071 La Coruña, Spain

## ABSTRACT

When experimental data for activity coefficients are analyzed,one typical feature of the variation of logarithm of mean ionic activity coefficient with ionic strength is the presence of a minimum in the curve. The presence of this minimum gives rise to a new point at which $\ln \gamma_{ \pm}$takes a value of zero in spite of the ionic strength being different from zero. In this paper the position of both points has been determined for 151 electrolytes using Pitzer equations to describe the dependence of $\ln \gamma_{ \pm}$on ionic strength.

## KEY WORDS

Pitzer equations, activity coefficients, ionic strength

## Introduction

Experimental determination of activity coefficients and their interpretation in the light of the current theories represent an outstanding topic in Solution Chemistry. The great ability to deal with data at high ionic strength, for both single and mixed electrolytes, explains the currently widespread use of the model proposed by Pitzer. As a matter of fact, the Pitzer equations are being successfully used in a large number of different fields, like Oceanography or Geochemistry, where complex saline solutions often appear [1]

When experimental activity coefficient data are analyzed, one typical feature of the variation of logarithm of mean ionic activity coefficient $\left(\ln \gamma_{ \pm}\right)$with ionic strength (I) is the presence of a minimum in the curve (fig. 1). This shape appears as a result of the balance among two opposite contributions, viz. a negative one, Debye-Huckel type, and one or more positive ones, arising from other kind of interactions, which, as a rule, are the so-called

## Corresponding author

## specific interactions.

Figure 1. General trend of $\ln \gamma_{ \pm}$vs Ionic Strength, showing the minimum and the interception point with $I$ axis

As it can be seen in figure 1, the presence of that minimum in the curves gives rise to a new particular point, the intersection of the curve with the ionic strength axis, $I_{c}$, at which $\ln \gamma_{ \pm}$takes a value of zero in spite of the ionic strength being different from zero.

In this paper, Pitzer equations have been used to evaluate the logarithm of the mean ionic activity coefficient $\ln \gamma_{ \pm}$of a series of 1:1 electrolytes, taken from [2], in order to determine the position of the two points with $\ln \gamma_{ \pm}=1$ and $\ln \gamma_{ \pm}=0$, on $\ln \gamma_{ \pm}$vs I plots.

## Methodology

The position of the minimum, $\mathrm{I}_{\text {min }}$, and the position of the intersection point, $\mathrm{I}_{\mathrm{c}}$, is determined by solving the equations

$$
\begin{equation*}
\frac{d \ln \gamma_{ \pm}}{d I}=0 \tag{1}
\end{equation*}
$$

and

$$
\begin{equation*}
\ln \gamma_{ \pm}=0 \tag{2}
\end{equation*}
$$

The dependence of $\ln \gamma_{ \pm}$vs ionic strength has been derived by means of Pitzer equations:

$$
\begin{equation*}
\ln \gamma_{M X}=f^{\gamma}+2 I B_{M X}+I^{2} B_{M X}^{\prime}+1.5 I^{2} C_{M X}^{\phi} \tag{3}
\end{equation*}
$$

where the different coefficients are defined in table 1 and the interaction parameters for each electrolyte were taken from tables 2, 3, 4 and 5 of [2].

Table 1. Coefficients appearing in Pitzer equation for activity coefficients.

| Coefficients of eq. 3 | First derivative |
| :--- | :--- |
| $f^{\gamma}=-A_{\phi}\left[\frac{\sqrt{I}}{1+1.2 \sqrt{I}}+\frac{2}{1.2} \ln (1+1.2 \sqrt{I}]\right.$ | $f^{\gamma}=-A_{\phi}\left(\frac{1.5+1.2 \sqrt{I}}{\sqrt{I}(1+1.2 \sqrt{I})^{2}}\right)$ |
| $B_{M X}=\beta_{M X}^{(0)}+\frac{\beta_{M X}^{(1)}}{2 I}[1-(1+1.2 \sqrt{I}) \exp (-2 \sqrt{I})]$ | $B_{M X}{ }^{\prime}=\frac{\beta_{M X}^{(1)}}{2 I^{2}}[-1+(1+1.2 \sqrt{I}+2 I) \exp (-2 \sqrt{I}]$ |
| $B_{M X}{ }^{\prime}=\frac{\beta_{M X}^{(1)}}{2 I^{2}}[-1+(1+1.2 \sqrt{I}+2 I) \exp (-2 \sqrt{I})]$ | $B_{M X}{ }^{\prime \prime}=\left(\frac{-\beta_{M X}^{(1)}}{I^{3}}\left[-1+(1+1.2 \sqrt{I}+2 I) e^{-2 \sqrt{I}]}-\frac{\beta_{M X}^{(1)}}{I^{3 / 2}} e^{-2 \sqrt{I}}\right)\right.$ |

Eqs (1) and (2) applied to eq. (3), in order to obtain the desired points, involves a numerical solution since solving them analytically is not possible. A program in Fortran was written to accomplish this task, where the subroutines rtsafe and dbrent from ref. [3] were used to find the intersection point and the position of the minimum, respectively.

Finally, the results were compared with those obtained by application of Bronsted equation, which is the single model which lets one solve analytically the singular points of $\ln \gamma_{ \pm} v s$. I curves.

## Results and Discussion

The values of $\mathrm{I}_{\text {min }}$ and $\mathrm{I}_{c}$ obtained from the calculation for the studied electrolytes appear in tables 2 and appendix, together with the values of $\ln \gamma_{ \pm}$at $\mathrm{I}_{\min }$ and the maximum value of ionic strength for the experimental data, $\mathrm{I}_{\mathrm{n}}$. In table 2 are listed electrolytes that show both minimum and intersection point, these values are given, ordered from the smallest to the greatest value of $I_{\text {min }}$. In appendix 1 appear the values of $I_{\min }$ and $I_{c}$ obtained for all the studied electrolytes. In some cases there is no minimum or intersection point or its value is out of the range of ionic strength used in the experiment, these cases are indicated in the table with the No label.

Table 2. Electrolytes that shows minimum and interception point in the interval 0-I . Ionic Strength in the minimum, $I_{\text {min }}$ and in the interception point with Ionic Strength axis, $I_{c}$, for the curves $\ln \gamma_{ \pm}$vs $I$, obtained from the solutions of eq. (1) and (2). $I_{n}$ is the maximum available ionic strength. The value of $\ln \gamma_{ \pm}\left(\mathrm{I}_{\min }\right)$ is listed too.

The following main features have been observed:
a) 71 electrolytes exhibit the minimum in the ionic strength range of $0<\mathbb{I}<I_{n}$
b) 52 electrolytes exhibit the minimum in the range of ionic strength between $\mathrm{I}=0$ and $\mathrm{I}=2 \mathrm{~mol} \mathrm{Kg}{ }^{-1}$.
c) 43 electrolytes fulfill the condition $\mathrm{I}_{\text {min }} \in(0.1-1.0)$.
d) The smallest value of $\mathrm{I}_{\text {min }}$ corresponds to $\mathrm{MgOHCl}-\mathrm{I}_{\text {min }}=0.08 \mathrm{~mol} \mathrm{Kg}^{-1}$ - and the greatest one to $\mathrm{CsBr},-\mathrm{I}_{\text {min }}=4.5 \mathrm{~mol} \mathrm{Kg}{ }^{-1}$.
e) 83 electrolytes show non or out of range minimum.
f) 32 electrolytes show both minimum and intersection point , these values are given in table 2, ordered from the smallest to the greatest value of $\mathrm{I}_{\min }$. Plots of $\ln \gamma_{ \pm}$vs. I for several electrolytes of this group are shown in fig. 2 to illustrate the behaviour.

Figure 2. Some representative curves of $1: 1$ electrolytes, it can be seen the minimum ( $\mathrm{Bu}_{4} \mathrm{NF}$ ) and the maximum $(\mathrm{NaOH})$ values for $\mathrm{I}_{\mathrm{c}}$.

According to fig. 3, a high correlation has been found between the position of the minimum of the curves, $\mathrm{I}_{\text {min }}$, and the intersection point, $\mathrm{I}_{\mathrm{c}}$, obtained by means of the Pitzer equations (table 2). The following correlation equation was obtained

$$
\begin{equation*}
\ln I_{c}=1.07(0.03)+1.77(0.03) \ln I_{\min } \quad r=0.99 \tag{4}
\end{equation*}
$$

where the error of the parameters are given into brackets.
This correlation may be justified in a simple way and in qualitative terms by use of the Bronsted equation $[4,5]$

$$
\begin{equation*}
\ln \gamma_{ \pm}=P \sqrt{I}+Q I \tag{5}
\end{equation*}
$$

where P and Q are constants at fixed pressure, temperature and solvent. This model is the only one that provides analytical solutions for both the position of the minimum and the intersection point, according to:

$$
\begin{equation*}
I_{\min }=\left[\frac{P}{2 Q}\right]^{2} \tag{6}
\end{equation*}
$$

and

$$
\begin{equation*}
I_{c}=\left[\frac{P}{Q}\right]^{2} \tag{7}
\end{equation*}
$$

Combination of both equations yields the theoretical relation:

$$
\begin{equation*}
I_{c}=4 I_{\min } \tag{8}
\end{equation*}
$$

which, in logarithmic form, becomes

$$
\begin{equation*}
\ln I_{c}=1.38+\ln I_{\min } \tag{9}
\end{equation*}
$$

which agrees quite closely with the experimental fit (eq. 4). However, it can be seen that eq.(4) and (9) refer to straight lines, but with different slopes and intercepts. In fact, it is not expected both expressions to be statistically comparable taking into account the simplicity of Bronsted model.

Figure 3. Plot of $\ln \left(\mathrm{I}_{c}\right)$ vs $\ln \left(\mathrm{I}_{\min }\right)$ according to Pitzer Model, see eq. (4).
